# COUNTING NUMBERS OF PERMUTATIONAL ISOMERS OF HETERO FULLERENES 

MODJTABA GHORBANI•, MARYAM JALALI<br>Institute of Nanoscience and Nanotechnology, University of Kashan, Kashan 87317-51167, Iran

#### Abstract

Hetero fullerenes are fullerenes where some of the carbon atoms are replaced by other atoms. Fripertinger applied SYMMETRICA to write some codes for computing the number of $\mathrm{C} 60-\mathrm{kBk}$ molecules, where B is a hetero-atom such as Si . (see H. Fripertinger, MATCH Commun. Math. Comput. Chem. 33, 121 (1996)) In this paper, the numbers of all $C_{12 n-\mathrm{k}} \mathrm{B}_{\mathrm{k}}$ hetero-fullerenes are computed, where $\mathrm{C}_{12 \mathrm{n}}$ is an infinite family of fullerenes. We apply the computer algebra system GAP to compute the number of permutational isomers of hetero fullerenes of the $\mathrm{C}_{60}$ fullerene with Ih point group symmetry.

(Received November 28, 2008; accepted December 4, 2008)
Keywords: Fullerene, Hetero Fullerene, Cycle Index, Permutation Group.

## 1. Introduction

Carbon exists in several forms in nature. One is the so-called fullerene which was discovered for the first time in $1985 .{ }^{1}$ Fullerenes are carbon-cage molecules in which a large number of carbon (C) atoms are bonded in a nearly spherically symmetric configuration. Fullerenes are molecules in the form of cage-like polyhedra, consisting solely of carbon atoms. Fullerenes $\mathrm{C}_{n}$ can be drawn for $n=20$ and for all even $n \geq 24$. They have $n$ carbon atoms, $3 n / 2$ bonds, 12 pentagonal and $n / 2-10$ hexagonal faces. The most important member of the family of fullerenes is $\mathrm{C}_{60}{ }^{2}$ Heterofullerenes are fullerene molecules in which one or more carbon atoms are replaced by heteroatoms such as boron or nitrogen, whose formation is a kind of "on-ball" doping of the fullerene cage.

Detecting symmetry of molecules is a well-studied problem with applications in a large number of areas. Randic ${ }^{3,4}$ and then Balasubramanian ${ }^{5-11}$ considered the Euclidean matrix of a chemical graph to find its symmetry. Here the Euclidean matrix of a molecular graph $G$ is a matrix $\mathrm{D}(\mathrm{G})=\left[\mathrm{d}_{\mathrm{ij}}\right]$, where for $\mathrm{i} \neq \mathrm{j}$, $\mathrm{d}_{\mathrm{ij}}$ is the Euclidean distance between the nuclei i and j . In this matrix $\mathrm{d}_{\mathrm{ii}}$ can be taken as zero if all the nuclei are equivalent. Otherwise, one may introduce different weights for different nuclei.

Suppose $\sigma$ is a permutation on $n$ atoms of the molecule under consideration. Then the permutation matrix $P \sigma$ is defines as $P_{\sigma}=\left[x_{i j}\right]$, where $x_{i j}=1$ if $i=\sigma(j)$ and 0 otherwise. It is easy to see that $\mathrm{P}_{\sigma} \mathrm{P} \tau=\mathrm{P}_{\sigma \tau}$, for any two permutations $\sigma$ and $\tau$ on n objects, and so the set of all $\mathrm{n} \times \mathrm{n}$ permutation matrices is a group isomorphic to the symmetric group $\mathrm{S}_{\mathrm{n}}$ on n symbols. It is a wellknown fact that a permutation $\sigma$ of the vertices of a graph $G$ belongs to its automorphism group if it satisfies $\mathrm{P}_{\sigma}{ }^{t} \mathrm{AP}_{\sigma}=A$, where A is the adjacency matrix of G . On the other hand, it is wellknown fact that for computing the symmetry of a molecule, it is sufficient to solve the matrix

[^0]equation $P^{t} E P=E$, where $E$ is the Euclidean matrix of the molecule under consideration and $P$ varies on the set of all permutation matrices with the same dimension as E .

Ashrafi and his co autors ${ }^{12-15}$ introduced some algorithms for computing the symmetry of molecules and applied them to compute the symmetry of some big fullerenes. We notice that for computing the number of isomers of a given fullerene molecule, we need to an efficient method for computing symmetry of fullerenes. Fripertinger ${ }^{16}$ computed the symmetry of some fullerenes and then applied SYMMETRICA ${ }^{17}$ to calculate the number of $\mathrm{C}_{60} \mathrm{H}_{\mathrm{k}} \mathrm{Cl}_{60-\mathrm{k}}$ molecules and Balasubramanian ${ }^{11}$ computed the number of $\mathrm{C}_{60} \mathrm{H}_{36}$ isomers.

Throughout this paper, our notation is standard and taken mainly from the standard book of the theory of graphs.

## 2. Main results

Groups are often used to describe symmetries of objects. This is formalized by the notion of a group action. Let $G$ be a group and $X$ a nonempty set. An action of $G$ on $X$ is denoted by GX and $X$ is called a G-set. It induces a group homomorphism $\varphi$ from $G$ into the symmetric group $S_{X}$ on $X$, where $\varphi(g) x=g x$ for all $x \in X$. The orbit of $x$ will be indicated as $x^{G}$ and defines as the set of all $\varphi(g) x, g \in G$. The set of all G-orbits will be denoted by $G \backslash \backslash X:=\left\{x^{G} \mid x \in X\right\}$. Suppose $g$ is a permutation of $n$ symbols with exactly $\lambda 1$ orbits of size $1, \lambda 2$ orbits of size $2, \ldots$, and $\lambda n$ orbits of size $n$. Then the cycle type of $g$ is defined as $1^{\lambda 1} 2^{\lambda 2} \ldots n^{\lambda n}$.

Enumeration of chemical compounds has been accomplished by various methods. The Polya-Redfield theorem has been a standard method for combinatorial enumerations of graphs, polyhedra, chemical compounds, and so forth. Combinatorial enumerations have found a wideranging application in chemistry, since chemical structural formulas can be regarded as graphs or three-dimensional objects.

Denote by Cm, n the set of all functions $\mathrm{f}:\{1,2, \ldots, \mathrm{~m}\} \rightarrow\left\{\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{n}}\right\}$. The action of $\mathrm{p} \in \mathrm{Sm}$ induced on $\mathrm{Cm}, \mathrm{n}$ is defined by $\hat{p}(f)=f o p^{-1}, f \in C_{m, n}$. Treating the colors $\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots$, $x_{n}$ that comprise the range of $f \in C m, n$ as, independent variables the weight of $f$ is $\mathrm{W}(\mathrm{f})=\prod_{i=1}^{m} f(i)$. Evidently, $\mathrm{w}(\mathrm{f})$ is a monomial of (total) degree m . Suppose G is a permutation group of degree $\mathrm{m}, \quad \hat{G}=\{\hat{p}: \mathrm{p} \in \mathrm{G}\}, \hat{p}$ is as defined above. Let $\mathrm{p}_{1}, \mathrm{p}_{2}, \ldots, \mathrm{p}_{\mathrm{t}}$ be the distinct orbits of $\hat{G}$. The weight of $\mathrm{p}_{\mathrm{i}}$ is the common value of $\mathrm{w}(\mathrm{f}), \mathrm{f} \in \mathrm{p}_{\mathrm{i}}$. The sum of the weights of the orbits is the pattern inventory

$$
\mathrm{W}_{\mathrm{G}}\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{n}}\right)=\sum_{i=1}^{t} w\left(p_{i}\right)
$$

Theorem. 1 (Pólya's Theorem ${ }^{18}$ ) If $G$ is a subgroup of $S_{m}$ then the pattern inventory for the orbits of $\mathrm{C}_{\mathrm{m}, \mathrm{n}}$ modula $\hat{G}$ is

$$
\mathrm{W}_{\mathrm{G}}\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{n}}\right)=\frac{1}{|G|} \sum_{p \in G} M_{1}^{C_{1}(p)} M_{2}^{C_{2}(p)} \ldots M_{m}^{C_{m}(p)}
$$

where $\mathrm{M}_{\mathrm{k}}=\mathrm{x}_{1}{ }^{\mathrm{k}}+\mathrm{x}_{2}{ }^{\mathrm{k}}+\ldots+\mathrm{x}_{\mathrm{n}}{ }^{\mathrm{k}}$, the $\mathrm{k}^{\text {th }}$ power sum of the x , , and $\left(C_{1}(\mathrm{p}), \ldots, C_{m}(\mathrm{p})\right)$ is the cycle type of the permutation p .
We now introduce the notion of cycle index. Let $G$ be a permutation group. The cycleindex of $G$ acting on $X$ is the polynomial $Z(G, X)$ over $Q$ in terms of in determinates $x_{1}, x_{2}, \ldots, x_{t}, t=|X|$, defined by $\mathrm{Z}(\mathrm{G}, \mathrm{X})=\frac{1}{|G|} \sum_{C \in \operatorname{Conj}(G)}|C| \prod_{i=1}^{t} x_{i}{ }^{C_{i}\left(g_{c}\right)}$, where $\operatorname{Conj}(\mathrm{G})$ is the set of all conjugacy classes $C$ of $G$ with representatives $g_{C} \in C$.

The dihedral group $\mathrm{D}_{\mathrm{n}}$ is the symmetry group of an n -sided regular polygon for $\mathrm{n}>1$. These groups are one of the most important classes of finite groups currently applicable in chemistry. For example $D_{3}, D_{4}, D_{5}$ and $D_{6}$ point groups are dihedral groups. One group
presentation for $D_{n}$ is $\left\langle x, y \mid x^{n}=y^{2}=e, y x y=x^{-1}\right\rangle$. This means that $D_{n}$ is generated by a two elements set $\{x, y\}$ with the condition $x^{n}=y^{2}=1$ and $y x y=x^{-1}$. In this section, an infinite class $C_{12 n}$ of fullerene molecules with exactly $12 n$ carbon atoms and symmetry group $D_{24}$ is constructed, Figure 1. To compute the number of isomers of these fullerenes, we first compute a permutation representation for the symmetry group of these fullerenes.
Consider the Graph of Fullerene $\mathrm{C}_{12 \mathrm{n}}$, Figure 1. From Figure 1, one can see that the generators of this group are as follows:

```
\sigma=(1,12n-5)(2,12n-4)(3,12n-3)...(12n-24,12n-18)(12n-22,12n-19)(12n-21,12n-20),
\tau=(1,12n-5,2,12n,3,12n-1,4,12n-2,5,12n-3,6,12n-4)...(12n-29,12n-25,12n-26,12n-18,12n-20,12n-19,
12n-22,12n-21,12n-24,12n-23,12n-28,12n-27).
```

Since $\sigma^{2}=\tau^{10}=$ identity and $\sigma^{-1} \tau \sigma=\tau^{-1}$, the symmetry group $G$ of these fullerenes is isomorphic to the dihedral group of order 24. In Table 1, the cycle types of elements of G are computed. Thus the cycle index of $G$ is computed as $Z(G, X)=\left(x_{1}{ }^{12 n}+6 x_{1}{ }^{2 n} x_{2}{ }^{5 n}+2 x_{6}{ }^{2 n}+2 x_{3}{ }^{4 n}+\right.$ $\left.7 x_{2}{ }^{6 n}+4 x_{12}{ }^{n}+2 x_{4}{ }^{3 n}\right) / 24$. But from the cycle indices one can compute the number of different colourings using $k$ colours via Pólya-theory by replacing each variable $x_{i}$ in the cycle index by 1 $+\mathrm{x}^{\mathrm{i}}$.

In what follows we prepare a GAP program to compute the number of hetero fullerenes for $\mathrm{C}_{12 \mathrm{n}}$. We mention here that our computations of symmetry properties and cycle indices of fullerenes were carried out with the use of GAP ${ }^{19,20}$. This software was constructed by the GAP team in Aachen. In Table 3, we apply this program to compute the number of hetero fullerenes for the case of $n=3$.

Table 1. Cycle Types of Elements of G.

| Fullerene | Cycle type | \#Permutations |
| :---: | :---: | :---: |
| $\mathrm{C}_{12 \mathrm{n}}$ | $1^{20 \mathrm{n}}$ | 1 |
|  | $1^{2 \mathrm{n}} 2^{9 \mathrm{n}}$ | 5 |
|  | $2^{10 \mathrm{n}}$ | 6 |
|  | $10^{2 \mathrm{n}}$ | 4 |
|  | $5^{4 \mathrm{n}}$ | 4 |

We now present a GAP program to compute the numbers of different fullerene molecules $\mathrm{C}_{12 \mathrm{n}}$ ${ }_{k} B_{k}$, for large $n$.
Program: A Gap Program for Counting the Number of Hetero Fullerene for $\mathrm{C}_{12 \mathrm{n}}$

            Print(i," 1 n ");
        od;
    return;
```

end;

Fig. 1. The Schlegel diagram of $C_{12 n}$.
To investigate the efficiency of this program, we consider the Buckminster fullerene $\mathrm{C}_{24}$, Figure 2. Fripertinger ${ }^{16}$ computed the cycle indices for the actions of the rotational group R and symmetry group $S$ on the set of all vertices as follows:

$$
\begin{aligned}
& \mathrm{Z}(\mathrm{G}, \mathrm{R})=\frac{1}{12}\left(2 \mathrm{x}_{6}{ }^{4}+2 \mathrm{x}_{3}{ }^{8}+4 \mathrm{x}_{2}{ }^{12}+\mathrm{x}_{1}{ }^{24}\right), \\
& \mathrm{Z}(\mathrm{G}, \mathrm{~S})=\frac{1}{2} Z(G, R)+\frac{1}{24}\left(4 \mathrm{x}_{12}{ }^{2}+2 \mathrm{x}_{4}{ }^{6}+6 \mathrm{x}_{1}{ }^{4} \mathrm{x}_{2}{ }^{10}\right) .
\end{aligned}
$$

Fig 2. The Fullerene $C_{24}$

We apply these cycle indices program to compute the number of permutational isomers of this fullerene. Our calculations are given in Table 2. Fripertinger in the mentioned paper computed these cycle indices and one can see that our calculations have the same results.

## Acknowledgement

We are very pleased from referees for helpful remarks. This research was in part supported by a grant from the Center of Excellence of Algebraic Methods and Applications of Isfahan University of Technology.
